TRAINING THE TACTICAL MIND:

WHAT BRAIN SCIENCE MEANS FOR SWAT OFFICERS

BY JEFF SELLEG

A SYNTHESIS OF PEER-REVIEWED RESEARCH FOR LAW ENFORCEMENT PROFESSIONALS

SWAT officers face some of the most mentally demanding challenges in law enforcement. In seconds, team members must assess rapidly changing threat information, make high-stakes decisions, regulate emotional responses, and remain aware of their surroundings under extreme stress. Physical conditioning has long been a fundamental part of tactical readiness — but a growing body of peer-reviewed research now strongly suggests that brain fitness should have an equal place in an operator's preparation.

The brain is trainable

More than five decades of neuroscience research has shown that the human brain is neuroplastic — capable of lasting structural and functional changes throughout adulthood. These changes include improvements in myelination, synaptogenesis, neurogenesis, processing speed, and network connectivity (Lundie et al., 2026). Just as physical exercise strengthens muscles and supports cardiovascular health, targeted cognitive training can enhance the brain's performance, resilience, and psychological well-being. The implications for high-stress occupations such as tactical law enforcement are significant.

Two validated approaches

Among the many cognitive training programs available, two have the strongest scientific evidence. BrainHQ is an adaptive, computerized training platform offering 29 exercises targeting attention, memory, processing speed, and social cognition. The program automatically adjusts to each user's performance level and generates personalized daily training schedules. SMART (Strategic Memory Advanced Reasoning Training) is a strategy-based program that focuses on three core cognitive skills: strategic attention, integrated reasoning, and innovation. SMART teaches individuals to filter information overload, synthesize meaning from complex inputs, and develop flexible solutions to new problems (Lundie et al., 2026). These two programs represent fundamentally different yet complementary approaches to enhancing brain function — one improving from the bottom up with adaptive exercises, the other from the top down through the habitual use of executive strategies.

What the research shows

Results from multiple randomized controlled trials (RCTs) show significant cognitive benefits for both programs. BrainHQ training has improved executive functions, processing speed, working memory, cognitive flexibility, and attentional control. SMART has documented gains in task switching, integrated reasoning, cognitive control, concept abstraction, and fluency (Lundie et al., 2026). For SWAT officers, these outcomes are not merely laboratory findings — they directly relate to the demands of rapidly evolving active threat response and tense, uncertain incidents such as hostage rescues, where split-second decision-making, impulse control, and adaptive thinking under stress are crucial.

Beyond raw cognitive performance, both programs have shown reductions in symptoms of depression and stress (Lundie et al., 2026). This is important because psychological distress is a well-known risk factor in law enforcement and is linked to impaired decision-making, decreased attentional control, and increased impulsivity — cognitive issues that directly threaten officer safety and tactical effectiveness.

Field evidence: The Warfighter Brain Fitness Study

The most directly relevant evidence for tactical populations comes from the Warfighter Brain Fitness (WBF) study, a large-scale implementation study conducted with National Guard service members across 14 states (Young et al., 2025). Using a crossover design, 406 healthy participants were randomly assigned to BrainHQ or SMART+ training over a six-month protocol. Outcomes were measured with the Brain-Health Index (BHI), a validated composite tool measuring three domains: clarity (cognitive performance and executive function), emotional balance (psychological well-being, including depression, anxiety, and stress), and connectedness (resilience traits such as social support, engagement in meaningful activities, life satisfaction, and happiness).

Participants showed significant improvements in connectedness — the study's primary resilience measure — at both three months (Cohen's d = .47) and six months (d = 0.51) relative to the waitlist control group (Young et al., 2025). By six months, there also were notable gains in overall BHI scores and emotional balance. The waitlist control group did not show significant improvements during the same period, suggesting that the changes were likely due to the training rather than the passage of time.

A secondary practical finding is that the two methods work well together: completing both BrainHQ and SMART+ resulted in greater improvements than doing either one alone, and the order in which they were done did not affect the outcomes (Young et al., 2025). Importantly, just 15 minutes of daily training over three months was enough to see measurable resilience gains — a level of effort that fits with operational schedules.

Relevance to law enforcement specifically

The importance of these findings for law enforcement extends beyond inference. A key benefit of cognitive training in law enforcement is its flexibility in presentation. Because brain fitness programs benefit healthy, non-clinical individuals, they can be marketed as performance-enhancement tools rather than mental health treatments — a distinction that is especially important in occupational cultures where seeking help is often stigmatized (Lundie et al., 2026). SWAT commanders and training managers can introduce brain fitness alongside physical training without raising concerns about career impact or professional reputation.

Limitations and honest caveats

Training managers should recognize the research's limitations before applying it. The WBF study had a 76% attrition rate from baseline to the end of the first three-month training period, partly attributed to competing demands on National Guard members, who effectively hold two jobs (Young et al., 2025). This attrition undermines confidence in long-term results and underscores the need for organized support, mandatory coaching check-ins, and reduced administrative tasks to maintain engagement. Additionally, much of the foundational cognitive training research was conducted with older or clinical populations, and robust long-term data on healthy, younger law enforcement officers are limited (Lundie et al., 2026). The causal links between laboratory-based cognitive improvements and field performance, such as tactical decision-making, have not yet been established and require further research.

Conclusion

The science of cognitive training is advancing quickly, and its implications for tactical law enforcement are too important to overlook. BrainHQ and SMART+ have demonstrated measurable improvements in executive functions, emotional regulation, and resilience that SWAT operators rely on. Just 15 minutes a day, four days a week, for three months is enough to begin improving brain health outcomes (Young et al., 2025). Physical fitness standards have long emphasized that readiness is developed before the call. The evidence now supports applying the same logic to the brain.

About the author

Jeff Selleg manages the BrainHQ implementation project for the NTOA. He began his career in law enforcement in 1996 and retired as a commander from the Port of Seattle (WA) Police Department in 2022. He served as a member of Valley Regional SWAT from 2000 to 2022, starting on the entry team and further serving as an explosive breacher, sniper, sniper team leader, entry team leader and team commander. Selleg also served as a patrol and administrative services commander with collateral duty commands over the Explosive Detection Canine Unit, the Bomb Disposal Unit and SWAT. He served as a member of the Washington State Tactical Officers Association board of directors from 2007 to 2020, including several years as president.

“Just 15 minutes of daily training over three months was enough to see measurable resilience gains — a level of effort that fits with operational schedules.”
